

Competition

Chapter 13

Modes of Competition

- **Interference:**

- ❖ Direct aggressive interaction between individuals.

- **Intraspecific:**

- ❖ Competition with members of own species.

- **Interspecific:**

- ❖ Competition between individuals of two species - reduces fitness of both.

Sometimes competition is obvious!

Sometimes it's not!
Where is competition
occurring here???

Intraspecific Competition Among Herbaceous Plants

- Plant growth rates and weights have been found to increase in low density populations.
 - Competition for resources is more intense at higher population densities.
 - Self-Thinning

**Lower density =
Larger individuals!**

a grass

Intraspecific Competition Among Planthoppers (herbivorous insect)

Competition led to:

1. Lower survivorship

2. Increased
development time

3. Reduced body size

Competitive Exclusion Principle

- Principle of Competitive Exclusion
 - ❖ Two species with identical niches cannot coexist indefinitely.

Which is the better competitor?

- One will be a better competitor and thus have higher fitness and eventually exclude the other.

Could *Chthamalus* ever be the better competitor???

Competition and Niches

- Competition can have significant ecological and evolutionary influences on the niches of species
 - ❖ Competition can restrict species to their realized niches.
 - Competition may also produce an evolutionary response in the competitor population.
 - Changes fundamental niche.

Niches and Competition Among Plants

- Two species of bedstraw (*Galium* spp.)
- Which species was a better competitor in basic soils? What about acidic?

Niche Overlap and Competition Between Barnacles

- *Connell* discovered interspecific competition in barnacles. *Balanus* plays a role in determining lower limit of *Chthamalus* within intertidal zone.

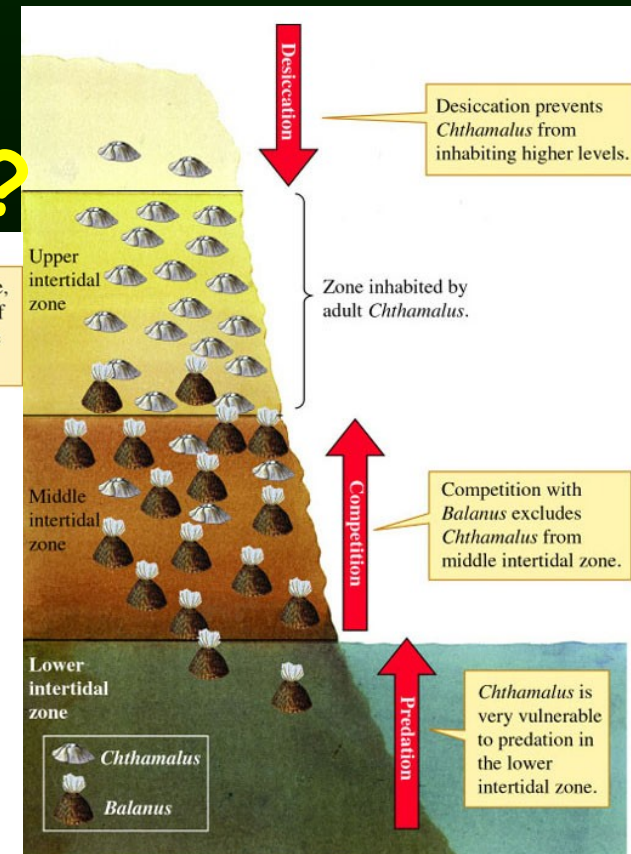

Does this explain everything???

Copyright © The McGraw-Hill Companies, Inc. Permission required for reproduction or display.

In the upper intertidal zone, removing *Balanus* had little effect on survival by *Chthamalus*.

In the middle intertidal zone, a much higher percentage of *Chthamalus* survived where *Balanus* was removed.

A dilemma!!!

- At the lowest levels in the lower intertidal, Chthamalus suffered high mortality even when Balanus was removed!!!
- Why???

There Once was an Ugly Barnacle.
He was so UGLY that everybody DIED.
THE END.

Competition is but one factor!

- Interspecific

fitness

doesn't wan
(hyena) help
or lion?

Therefore
beneficial

primary

Character displacement can lead to less interspecific competition

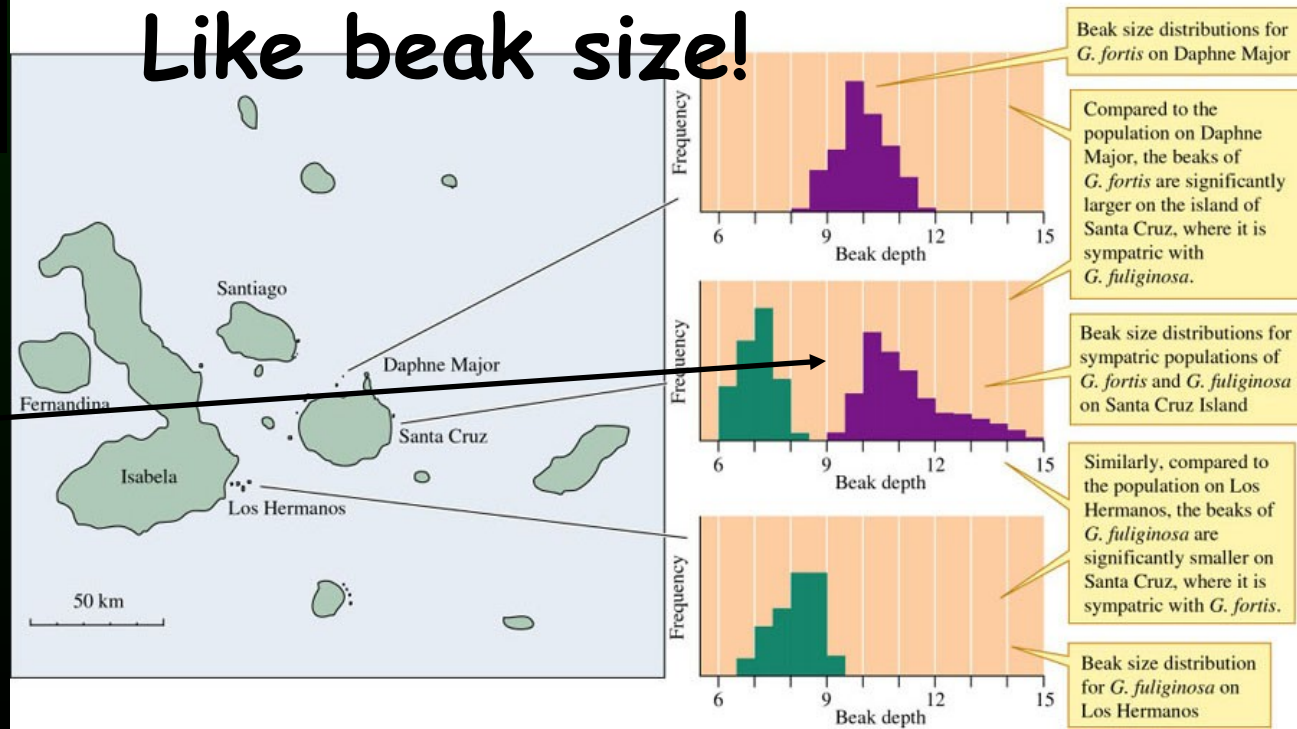

Character Displacement

Change in physical characteristic of a population as a result of natural selection - leads to less interspecific competition

Sympatric - occur in the same area and encounter each other

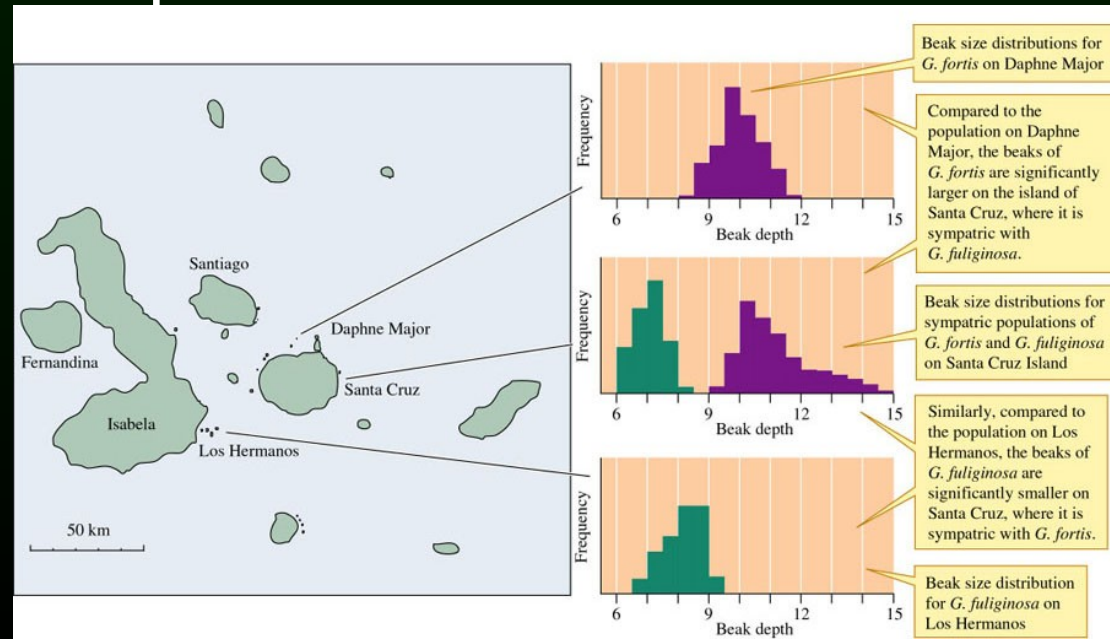

Like beak size!

Character Displacement

- Necessary criteria:
 1. Morphological differences between sympatric species are greater than differences between allopatric (don't occur in same area) populations.
 2. There are genetic differences between sympatric and allopatric populations.
 3. Differences between sympatric and allopatric populations evolved in place

Does the finch example work???

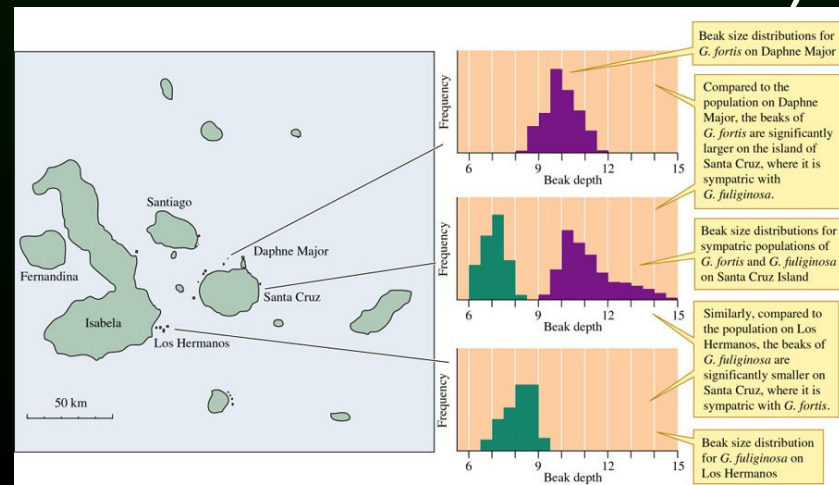

Necessary criteria for character displacement (cont'd)

4. Variation in the character must have an impact on the use of resources
5. Must be demonstrated competition for the resource and competition must be directly correlated with character similarity
6. Differences in character cannot be explained by differences in resources available to each of the populations (i.e. fewer seeds on one island or another)

Does the
finch
example
work???

YES!!!

The conclusion!!!

- Competition has a great effect on many populations!

However...competition is but one factor!
