

# Succession and Stability

## Chapter 20

**Primary Succession** Primary succession occurs on newly exposed surfaces, such as this newly deposited volcanic rock and ash. A volcanic eruption destroys the previous ecosystem (1). The first organisms to appear are lichens (2). Mosses soon appear, and grasses take root in the thin layer of soil (3). Eventually, tree seedlings and shrubs sprout among the plant community (4). **Predicting** What types of animals would you expect to appear at each stage, and why?

# Introduction

- **Succession**: Gradual change in plant and animal communities in an area following disturbance.
  - ❖ **Primary succession** on newly exposed geological substrates.
  - ❖ **Secondary succession** following disturbance that does not destroy soil.
- **Climax Community**: Late successional community that remains stable until disrupted by disturbance.

# Community Changes During Succession

- Succession leads to climax community

1500 years at  
Glacier Bay

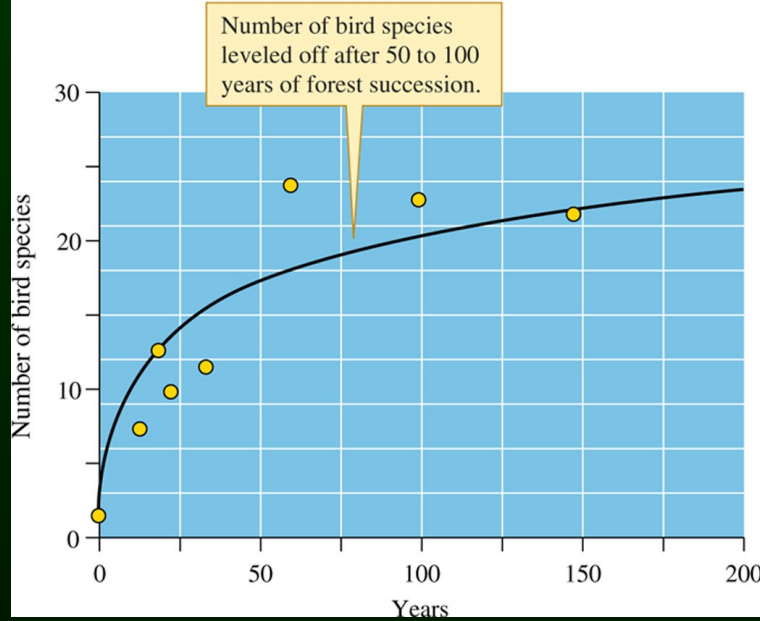

3 years in the  
intertidal

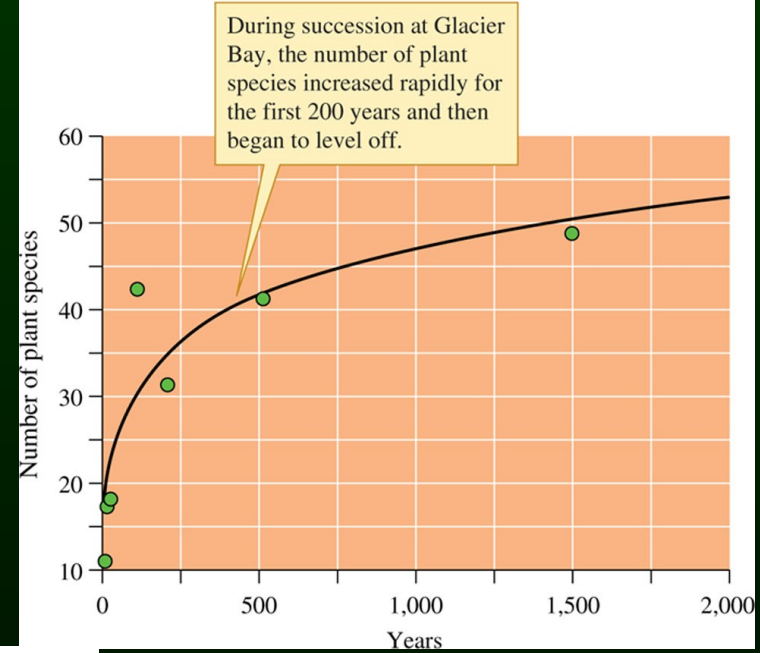

However, all succession shows an increase in species diversity over time!

The timing of increasing species richness differs among plant growth forms.

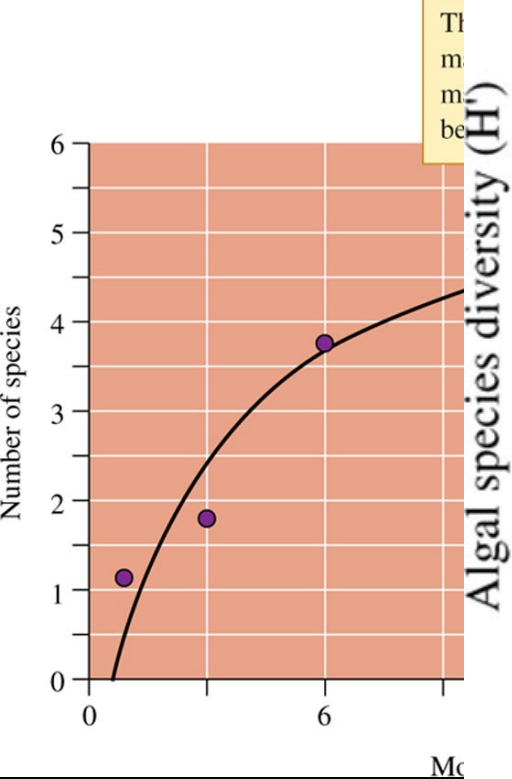

Number of woody plant species begins to level off after about 100 to 150 years.

Increases in species diversity over time!

<2 months in desert stream!!!

What factors into succession???

# Ecosystem Changes During Succession

- Ecosystem changes during succession include increases in biomass, primary production, respiration, and nutrient retention

- Physical and biological systems are inseparable.

Copyright © The McGraw-Hill Companies, Inc. Permission required for reproduction or display.

During succession, nitrogen, moisture, and organic matter content increased, ...

... while phosphorus content, pH, and bulk density decreased.

(Pioneer = 0 years → Spruce = 200 + years)

# Model of Ecosystem Recovery from Disturbance (Forest – 200 years)

Copyright © The McGraw-Hill Companies, Inc. Permission required for reproduction or display.

According to the biomass accumulation model, disturbing a forest ecosystem will induce a series of distinct recovery phases.

Following disturbance, the ecosystem will reorganize.

Next, biomass will increase.

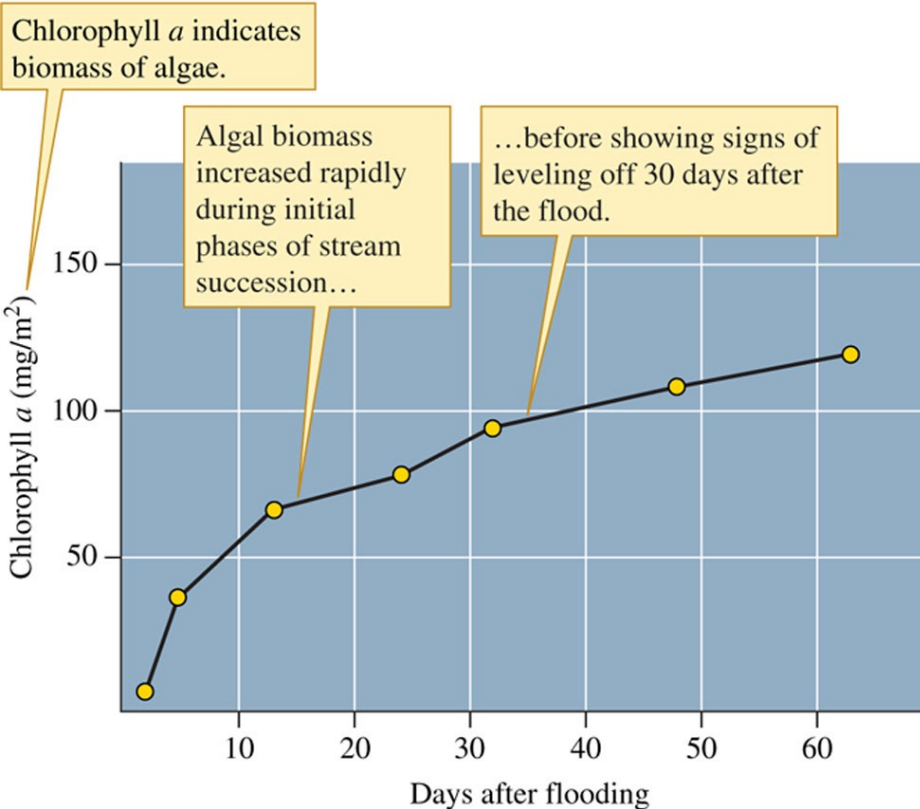

Biomass will decline during transition...

...to a steady state phase.

# Does this model work in our under 2-month successional sequence???

...to a steady state phase.

# Mechanisms of Succession – it's not a random change in species over time!!!

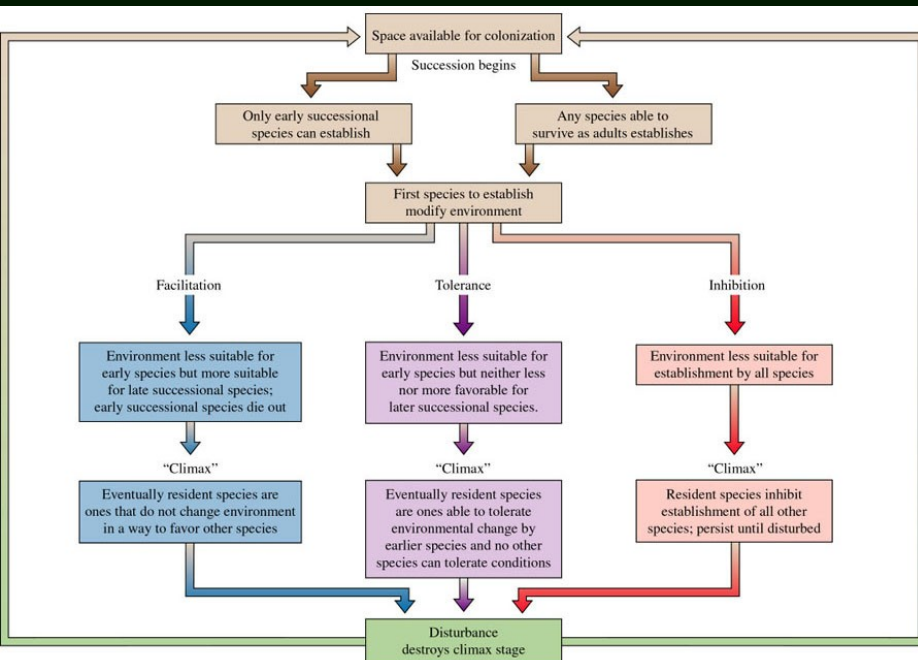

## Facilitation

- Proposes many species may attempt to colonize newly available space.
  - ❖ Only certain species will establish.
    - Colonizers “Pioneer Species” modify environment so it becomes less suitable for themselves and more suitable for species of later successional stages.

# Tolerance

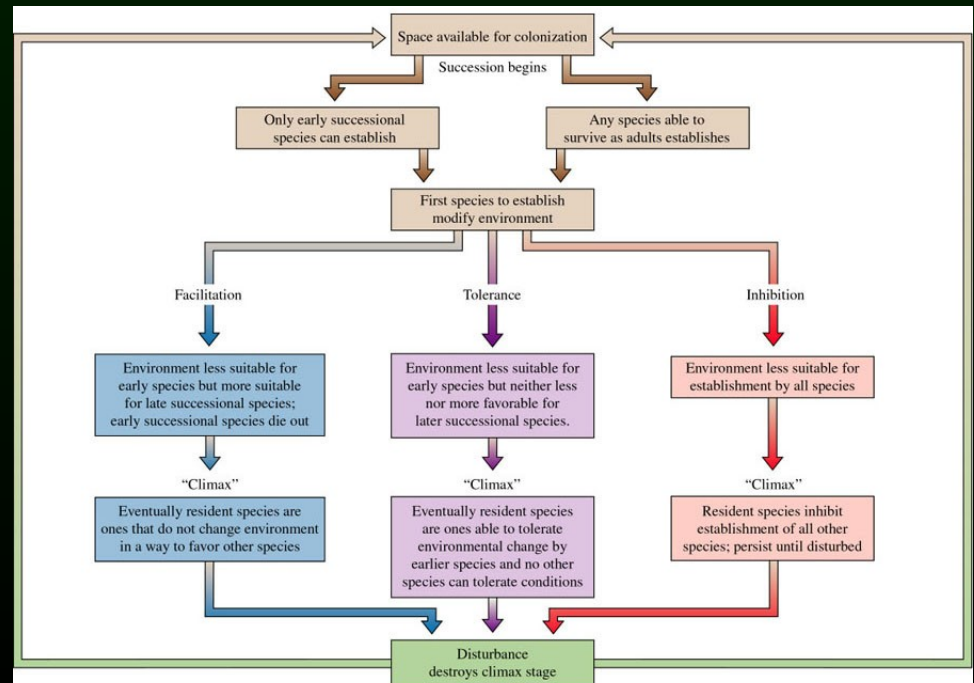

- Initial stages of colonization are not limited to pioneer species.
  - ❖ Early successional species do not facilitate later successional species.
  - ❖ Not as supported by studies as the other two models

# Inhibition

- Early occupants of an area modify the environment in a way that makes it less suitable for both early and late successional species.
- ❖ Early arrivals inhibit colonization by later arrivals.
- ❖ Assures late successional species dominate an area because they live a long time and resist damage by physical and biological factors.

# Successional Mechanisms in Rocky Intertidal Zone (found elsewhere too!)

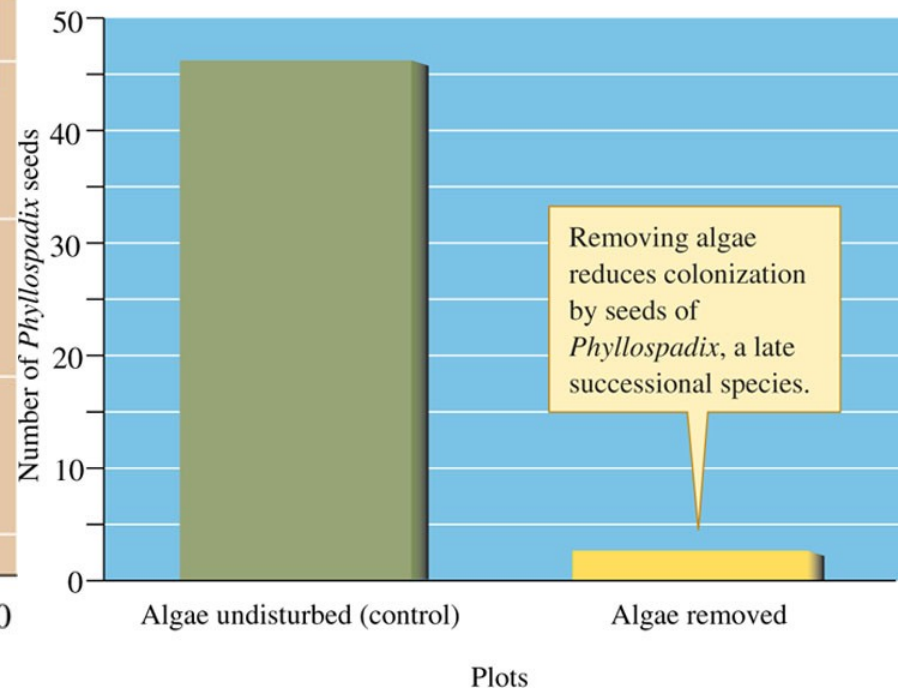

- Evidence of inhibition and facilitation!

You can even find both in some cases since succession can involve many species over time!

# Community and Ecosystem Stability

- Community stability may be due to lack of disturbance or community resistance or resilience in the face of disturbance

## Some definitions -

- **Stability**: Absence of change (ex. deep sea).
- **Resistance**: Ability to maintain structure and function in face of potential disturbance.
- **Resilience**: Ability to recover from disturbance.

# One major problem with successional studies

- Hint – most successional studies have been successfully done in the intertidal.

Most  
successional  
changes can't  
be seen in  
the short  
term!
