

How Cells Release Chemical Energy – Cellular Respiration

Overview of Carbohydrate Breakdown Pathways

- Photoautotrophs make ATP during photosynthesis and use it to synthesize glucose and other carbohydrates
 - Most organisms, including photoautotrophs, make ATP by breaking down glucose and other organic compounds
-

Comparison of the Main Pathways

- **Aerobic respiration**

- **Aerobic** metabolic pathways (using oxygen) are used by most eukaryotic cells

- **Fermentation**

- **Anaerobic** metabolic pathways (occur in the absence of oxygen) are used by prokaryotes and protists in anaerobic habitats
-

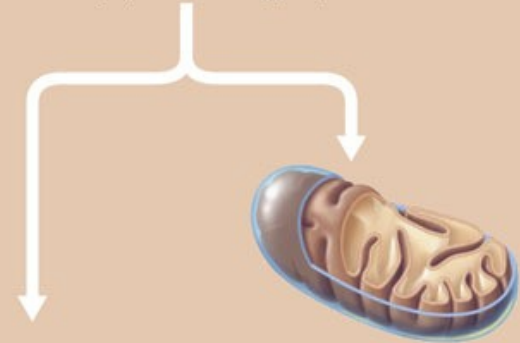

Comparison of the Main Pathways

- Aerobic respiration and fermentation both begin with **glycolysis**, which converts one molecule of glucose into two molecules of **pyruvate**
 - After glycolysis, the two pathways diverge
 - Fermentation is completed in the cytoplasm, yielding 2 ATP per glucose molecule
 - Aerobic respiration is completed in mitochondria, yielding 36 ATP per glucose molecule
-

Comparison of the Main Pathways

A Carbohydrate breakdown pathways start in the cytoplasm, with glycolysis.

B Fermentation pathways are completed in the semi-fluid matrix of the cytoplasm.

C In eukaryotes, aerobic respiration is completed inside mitochondria.

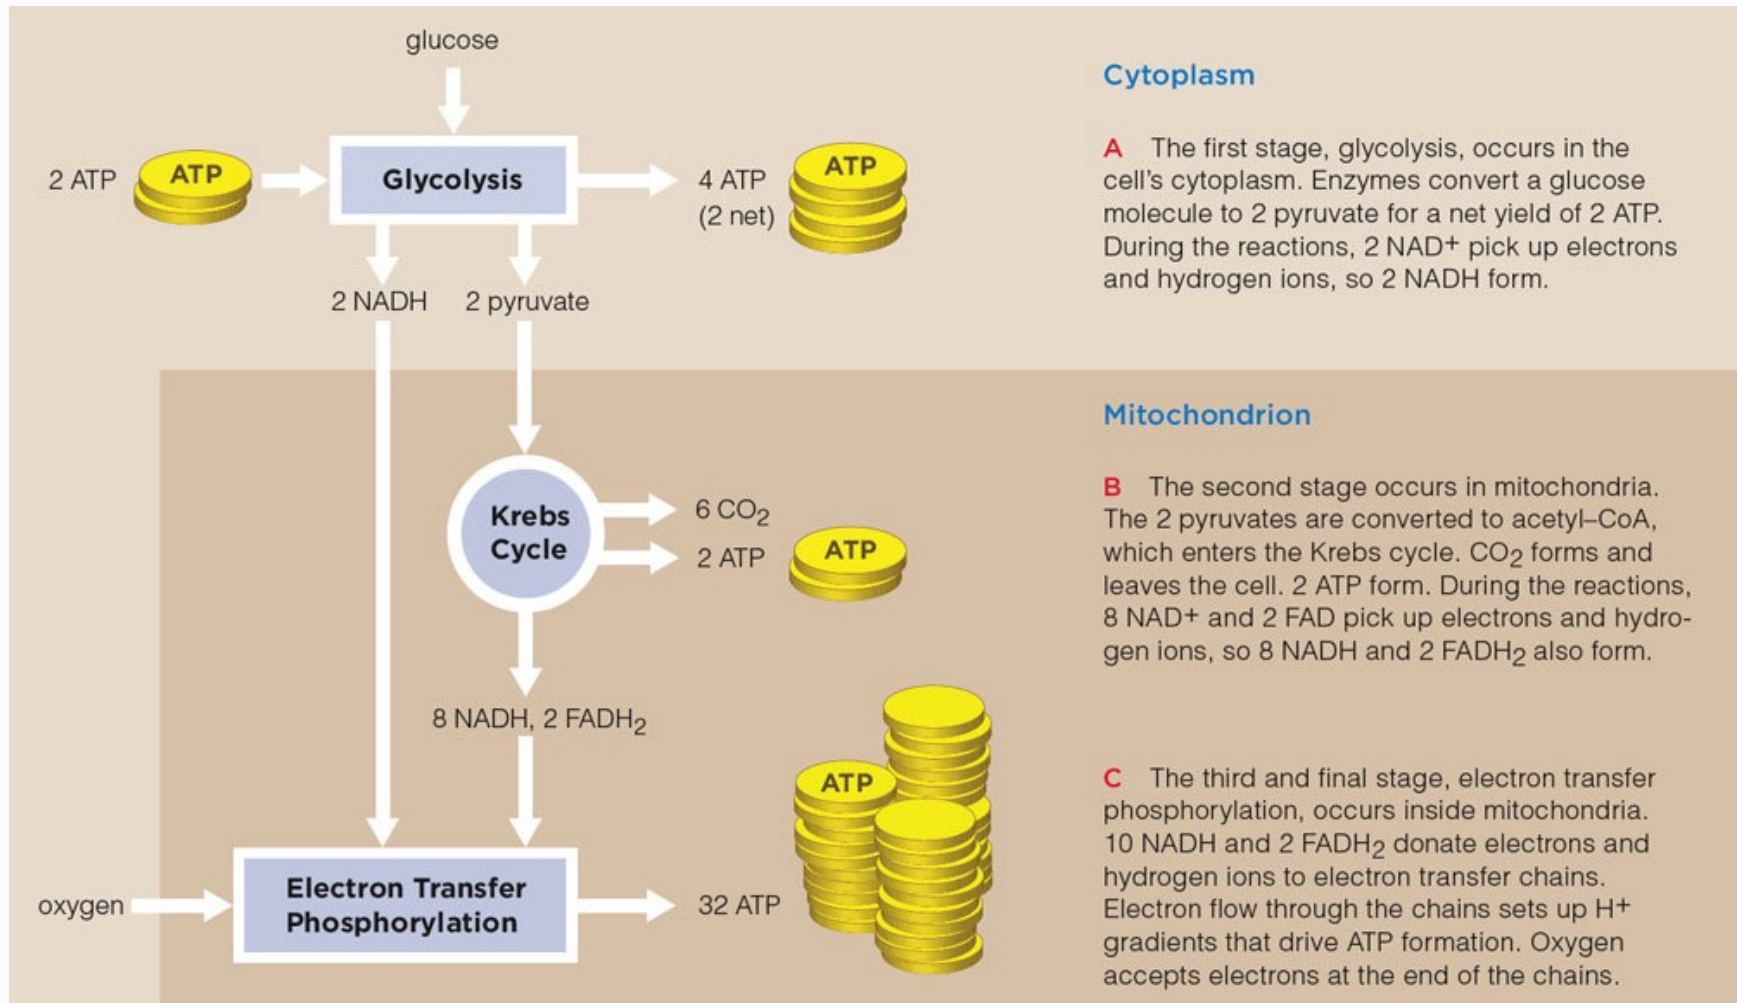

Overview of Aerobic Respiration

- Three stages
 - Glycolysis
 - Acetyl-CoA formation and Krebs cycle
 - Electron transfer phosphorylation (ATP formation)

- Coenzymes NADH and FADH₂ carry electrons and hydrogen
-

Overview of Aerobic Respiration

Cytoplasm

A The first stage, glycolysis, occurs in the cell's cytoplasm. Enzymes convert a glucose molecule to 2 pyruvate for a net yield of 2 ATP. During the reactions, 2 NAD⁺ pick up electrons and hydrogen ions, so 2 NADH form.

Mitochondrion

B The second stage occurs in mitochondria. The 2 pyruvates are converted to acetyl-CoA, which enters the Krebs cycle. CO₂ forms and leaves the cell. 2 ATP form. During the reactions, 8 NAD⁺ and 2 FAD pick up electrons and hydrogen ions, so 8 NADH and 2 FADH₂ also form.

C The third and final stage, electron transfer phosphorylation, occurs inside mitochondria. 10 NADH and 2 FADH₂ donate electrons and hydrogen ions to electron transfer chains. Electron flow through the chains sets up H⁺ gradients that drive ATP formation. Oxygen accepts electrons at the end of the chains.

Key Concepts:

Energy From Carbohydrate Breakdown

- *Various degradative pathways convert the chemical energy of glucose and other organic compounds to the chemical energy of ATP*
 - *Aerobic respiration yields the most ATP from each glucose molecule; in eukaryotes, it is completed inside mitochondria*
-

Glycolysis – Glucose Breakdown Starts

- Glycolysis starts and ends in the cytoplasm of all prokaryotic and eukaryotic cells
 - An energy investment of ATP starts glycolysis
-

Glycolysis

- Two ATP are used to split glucose and form 2 PGAL, each with one phosphate group
 - Enzymes convert 2 PGAL to 2 PGA, forming 2 NADH
 - Four ATP are formed by **substrate-level phosphorylation** (net 2 ATP)
 - Enzymes of glycolysis use two ATP to convert one molecule of **glucose** to two molecules of three-carbon **pyruvate**
-

Glycolysis

Products of Glycolysis

- Net yield of glycolysis:
 - 2 pyruvate, 2 ATP, and 2 NADH per glucose
 - Pyruvate may:
 - Enter fermentation pathways in cytoplasm
 - Enter mitochondria and be broken down further in aerobic respiration
-

Glycolysis Occurs in Two Stages

- 1. Energy-requiring steps
 - ATP energy activates glucose and its six-carbon derivatives
- 2. Energy-releasing steps
 - The products of the first part are split into three-carbon pyruvate molecules
 - ATP and NADH form

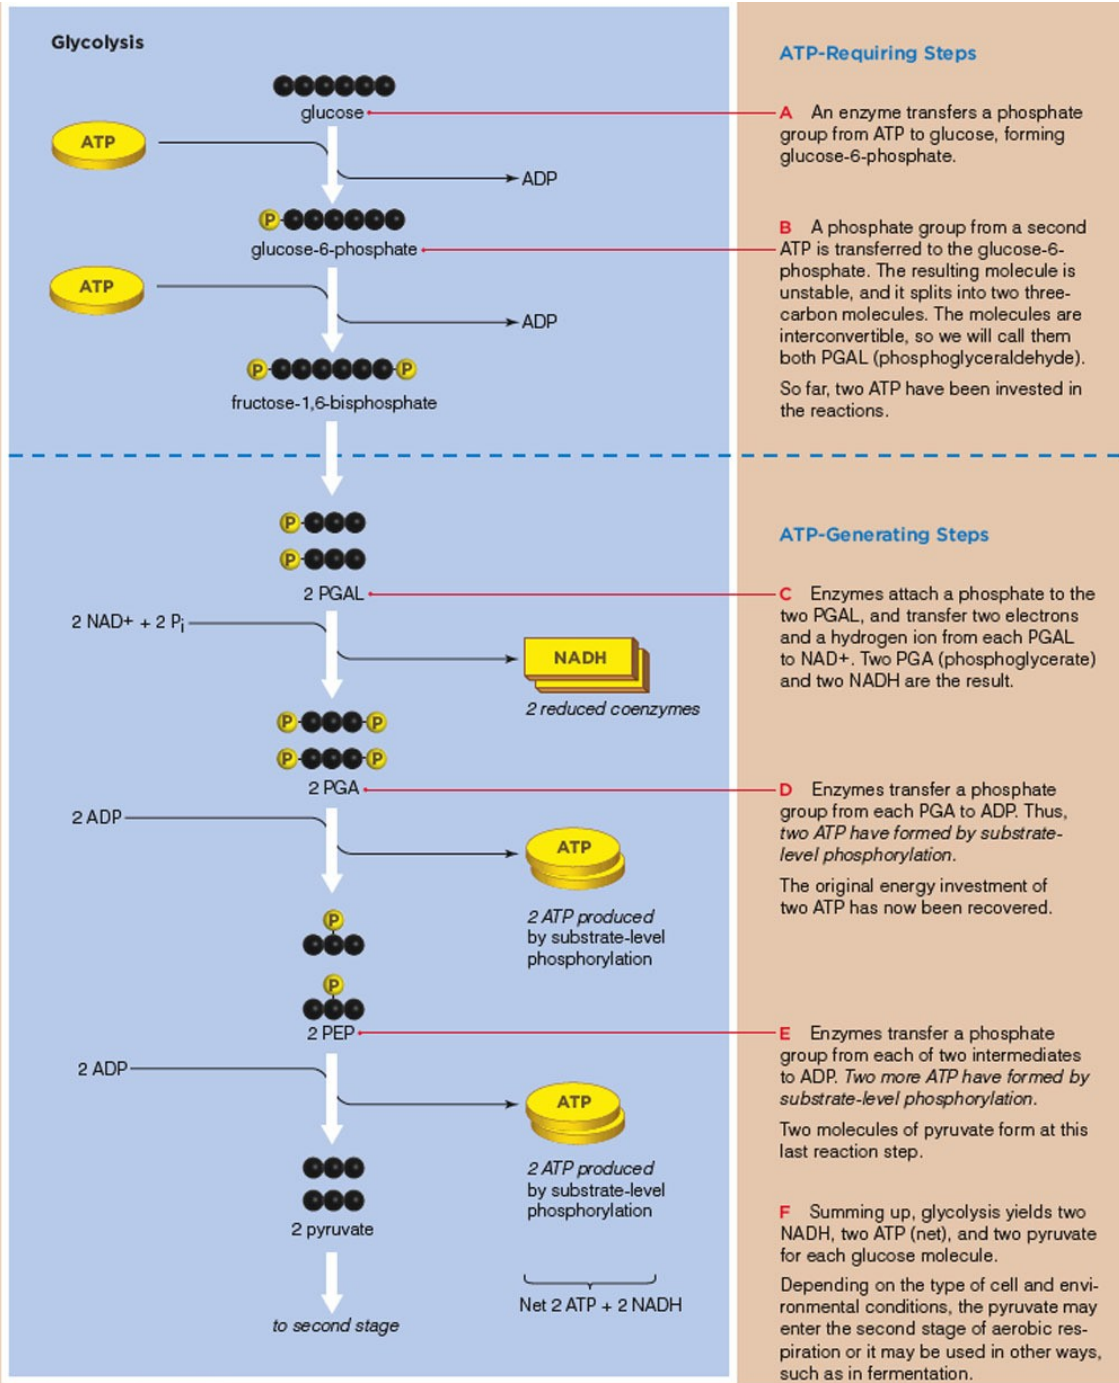

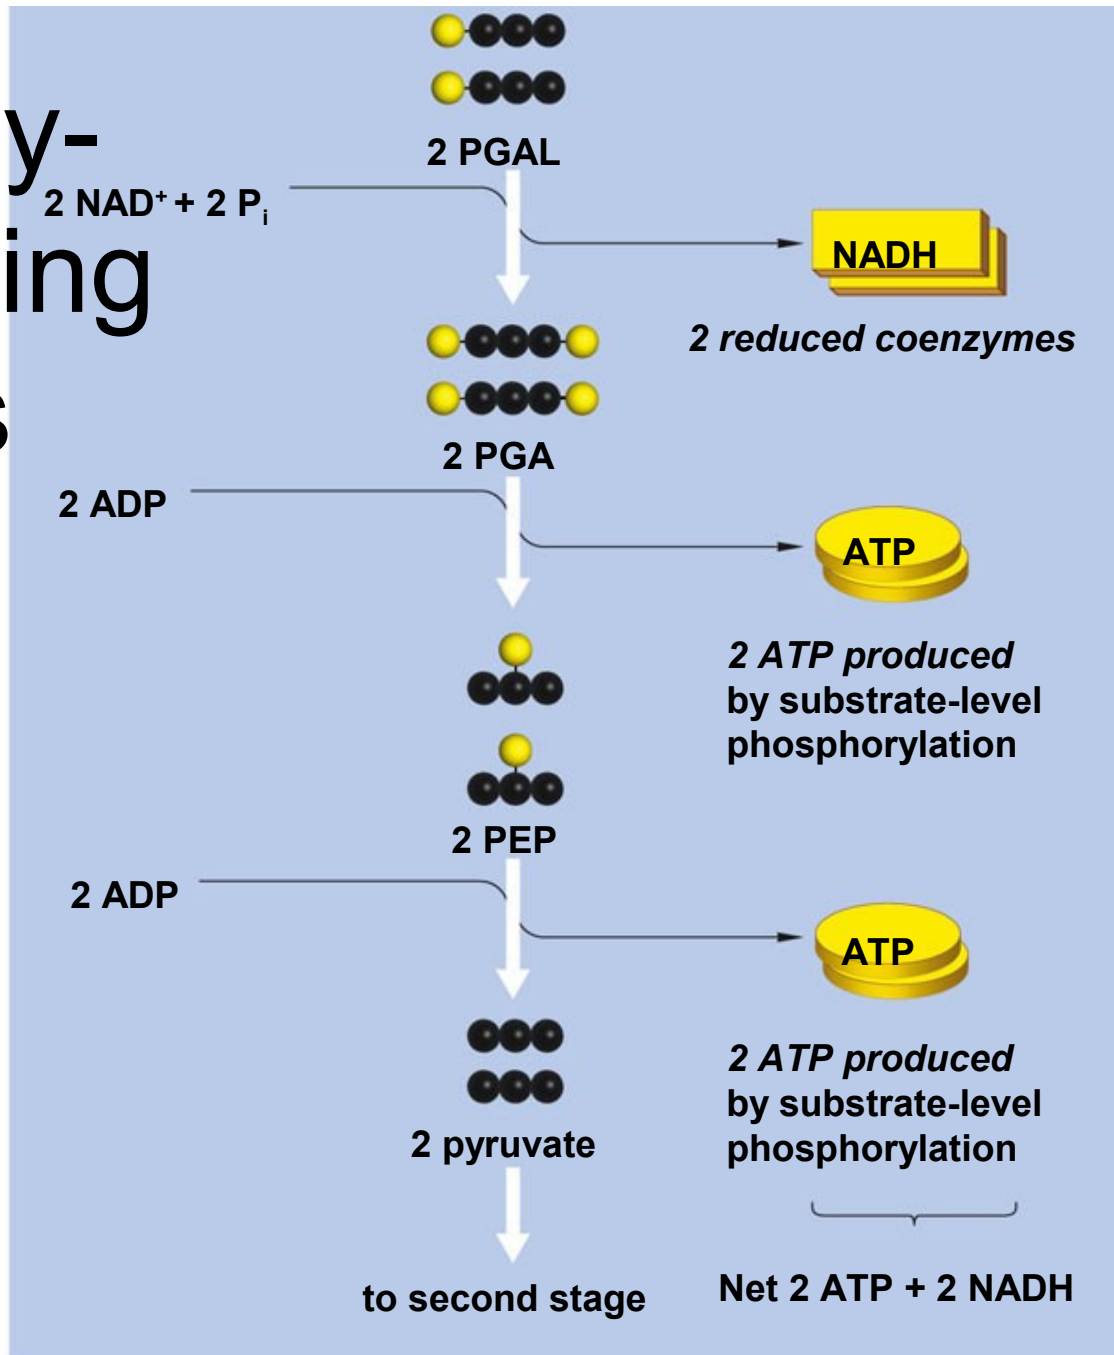

Fig. 8-4b, p. 127

Glycolysis

Energy-Requiring Steps

Energy-Releasing Steps

Key Concepts: Glycolysis

- *Glycolysis is the first stage of aerobic respiration and of anaerobic routes such as fermentation pathways*
 - *Enzymes of glycolysis convert glucose to pyruvate*
 - *As enzymes break down glucose to pyruvate, the coenzyme NAD^+ picks up electrons and hydrogen atoms*
 - *Net energy yield is two ATP*
-

Second Stage of Aerobic Respiration

- The second stage of aerobic respiration finishes breakdown of glucose that began in glycolysis
 - More ATP is formed
 - More coenzymes are reduced
 - Occurs in mitochondria
 - Includes two stages: acetyl CoA formation and the Krebs cycle (each occurs twice in the breakdown of one glucose molecule)
-

Acetyl CoA Formation

- In the inner compartment of the mitochondrion, enzymes split pyruvate, forming acetyl CoA and CO_2 (which diffuses out of the cell)
 - NADH is formed
-

The Krebs Cycle – 10.05, 10.06

■ **Krebs cycle**

- A sequence of enzyme-mediated reactions that break down 1 acetyl CoA into 2 CO₂
 - Oxaloacetate is used and regenerated
 - 3 NADH and 1 FADH₂ are formed
 - 1 ATP is formed
 - **DOUBLE THIS FOR EACH MOLECULE OF GLUCOSE!!!**
-

Inside a Mitochondrion

A An inner membrane divides a mitochondrion's interior into two compartments. The second and third stages of aerobic respiration take place at this membrane.

B The second stage starts after membrane proteins transport pyruvate from the cytoplasm to the inner compartment. Six carbon atoms enter these reactions (in two molecules of pyruvate), and six leave (in six CO₂). Two ATP form and ten coenzymes are reduced.

Krebs Cycle

- Each turn of the Krebs cycle, one **acetyl-CoA** is converted to two molecules of **CO₂**
 - DOUBLE THIS FOR EACH MOLECULE OF GLUCOSE!
 - After two cycles
 - Two pyruvates are dismantled
 - Glucose molecule that entered glycolysis is fully broken down
-

Little Johnny Krebs

Acetyl CoA Formation and the Krebs Cycle

A An enzyme splits a pyruvate molecule into a two-carbon acetyl group and CO_2 . Coenzyme A binds the acetyl group (forming acetyl-CoA). NAD^+ combines with released hydrogen ions and electrons, forming NADH.

B The Krebs cycle starts as one carbon atom is transferred from acetyl-CoA to oxaloacetate. Citrate forms, and coenzyme A is regenerated.

C A carbon atom is removed from an intermediate and leaves the cell as CO_2 . NAD^+ combines with released hydrogen ions and electrons, forming NADH.

D A carbon atom is removed from another intermediate and leaves the cell as CO_2 , and another NADH forms.

Pyruvate's three carbon atoms have now exited the cell, in CO_2 .

1. Remember that there are 2 pyruvate molecules from glycolysis!!!

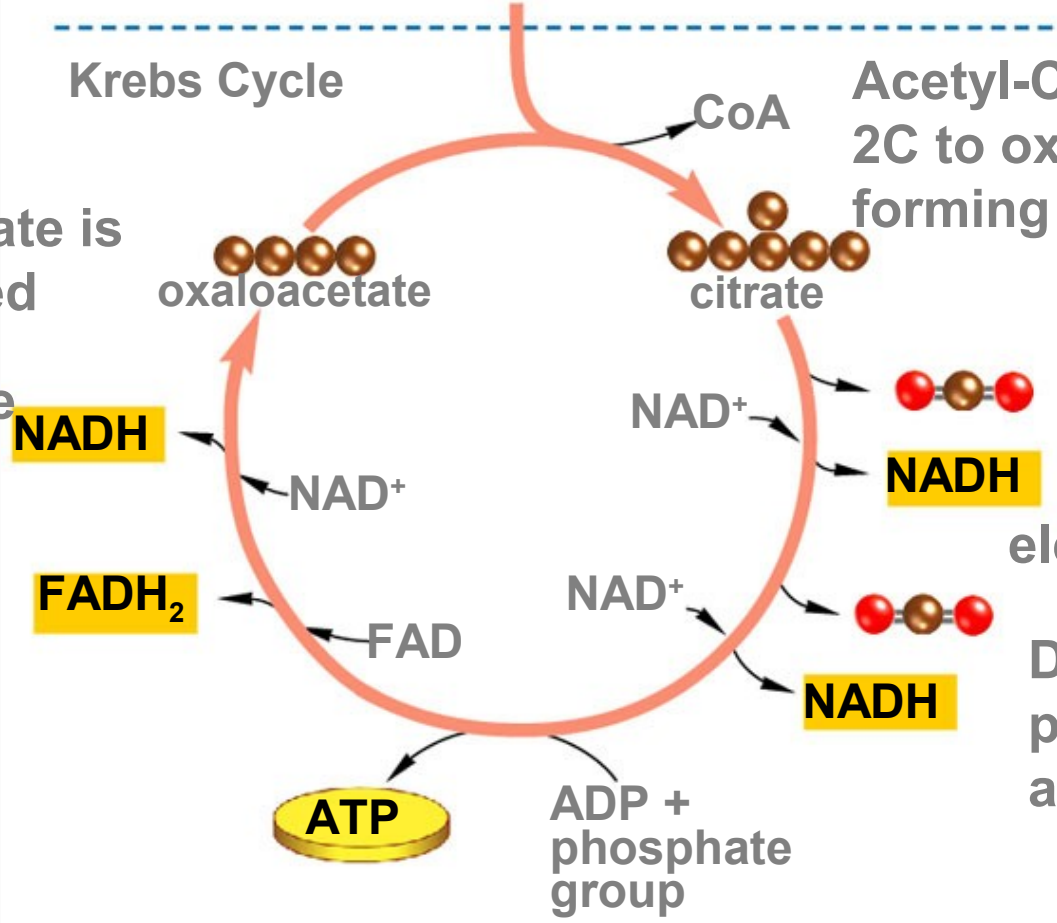

Krebs Cycle

Acetyl-CoA transfers 2C to oxaloacetate, forming citrate (6C)

Oxaloacetate is regenerated

You know the drill!!!

FAD picks up hydrogen and electrons, forming FADH₂

CO₂ released
NAD⁺ picks up hydrogen and electrons, forming NADH

Ditto! – C's of pyruvate are now all gone!

Substrate-level phosphorylation

Net Results

- Second stage of aerobic respiration results in
 - Six CO_2 , two ATP, eight NADH, and two FADH_2 for every two pyruvates
 - Adding the yield from glycolysis, the total is
 - Twelve reduced coenzymes and four ATP for each glucose molecule
 - Coenzymes deliver electrons and hydrogen to the **third stage of reactions**
-

Animation: Krebs cycle overview

Aerobic Respiration's Big Energy Payoff

- Many ATP are formed during the third and final stage of aerobic respiration
 - **Electron transfer phosphorylation**
 - Occurs in mitochondria
 - Results in attachment of phosphate to ADP to form ATP
-

Electron Transfer Phosphorylation

- Coenzymes NADH and FADH_2 donate electrons and H^+ to electron transfer chains
 - Active transport forms a H^+ concentration gradient in the outer mitochondrial compartment
 - H^+ follows its gradient through ATP synthase, which attaches a phosphate to ADP
 - Finally, oxygen accepts electrons and combines with H^+ , forming water
-

Creating an H⁺ Gradient

As electrons go through the transport chain (supplied by NADH & FADH₂), H⁺ gets shuttled out

ATP Formation

H^+ concentration is now greater in the outer compartment. H^+ follows these gradients through ATP synthases to the interior, forming ATP

Electron Transfer Phosphorylation

Summary: The Energy Harvest

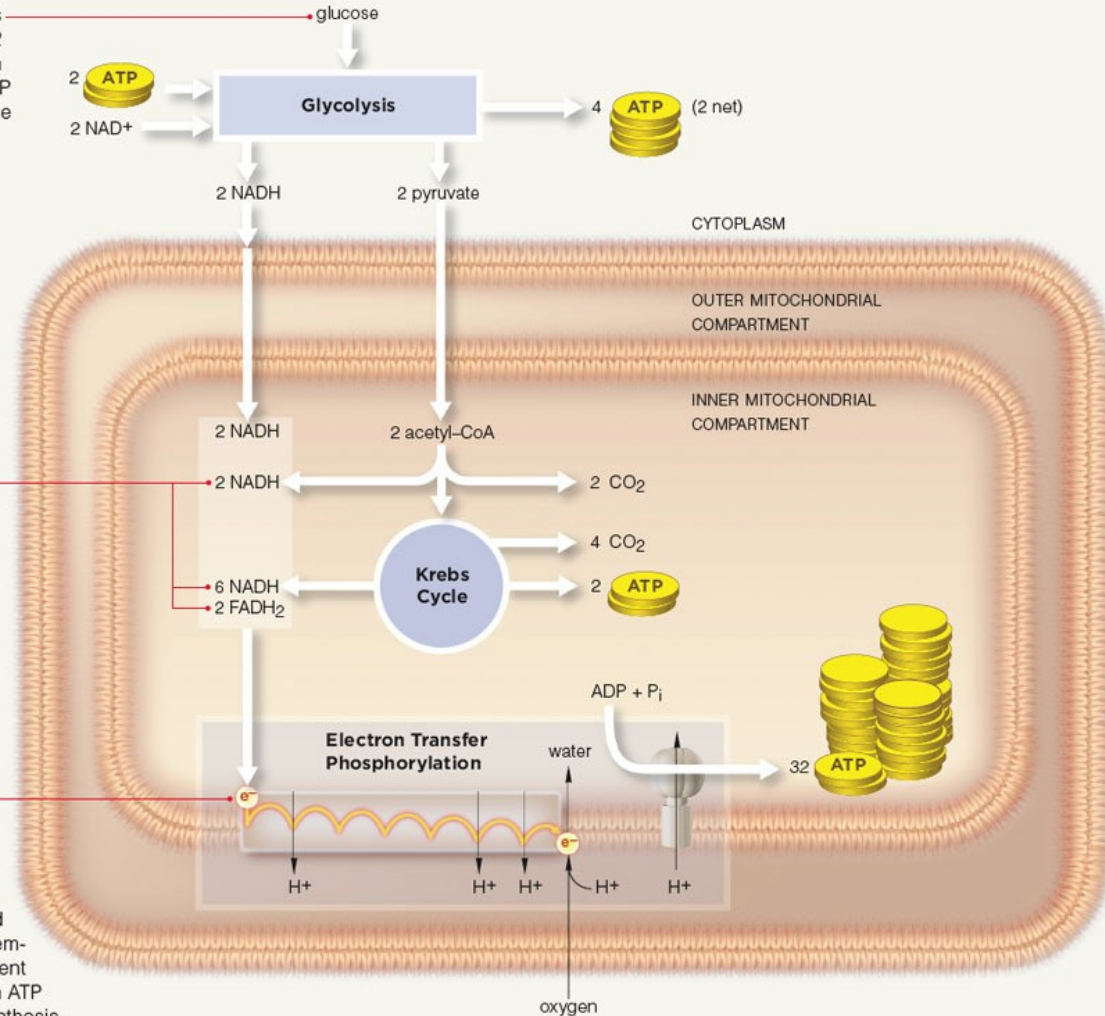

- Typically, the breakdown of one glucose molecule yields 36-38 (for the class, we'll call it 36) ATP based on the type of cell.
 - Glycolysis: 2 ATP
 - Acetyl CoA formation and Krebs cycle: 2 ATP
 - Electron transfer phosphorylation: 32 ATP
-

Summary: Aerobic Respiration

A First stage: Glucose is converted to 2 pyruvate; 2 NADH and 4 ATP form. An energy investment of 2 ATP began the reactions, so the net yield is 2 ATP.

B Second stage: 10 more coenzymes accept electrons and hydrogen ions during the second-stage reactions. All six carbons of glucose leave the cell (as 6 CO₂), and 2 ATP form.

C Coenzymes donate electrons and hydrogen ions to electron transfer chains. Energy lost by the electrons as they flow through the chains is used to move H⁺ across the membrane. The resulting gradient causes H⁺ to flow through ATP synthases, driving ATP synthesis.

Key Concepts:

How Aerobic Respiration Ends

- *The final stages of aerobic respiration break down pyruvate to CO₂*
 - *Many coenzymes that become reduced deliver electrons and hydrogen ions to electron transfer chains; energy released by electrons flowing through the chains is captured in ATP*
 - *Oxygen accepts electrons at ends of the chains*
-

Anaerobic Energy-Releasing Pathways

- Fermentation pathways break down carbohydrates without using oxygen
- The final steps in these pathways regenerate NAD^+ but do not produce ATP

■ Only used by simple organisms. You'll never see an anaerobic Renfield

Fermentation Pathways

- Glycolysis is the first stage of fermentation
 - Forms 2 pyruvate, 2 NADH, and 2 ATP
 - Pyruvate is converted to other molecules, but is not fully broken down to CO₂ and water
 - Regenerates NAD⁺ but doesn't produce ATP
 - Provides enough energy for some single-celled anaerobic species
-

Two Pathways of Fermentation

■ **Alcoholic fermentation**

- Pyruvate is split into acetaldehyde and CO_2
- Acetaldehyde receives electrons and hydrogen from NADH, forming NAD^+ and ethanol

■ **Lactate fermentation**

- Pyruvate receives electrons and hydrogen from NADH, forming NAD^+ and lactate
-

Two Pathways of Fermentation

Alcoholic Fermentation

The Twitchers

- Slow-twitch muscle fibers (“red” muscles) make ATP by aerobic respiration
 - Have many mitochondria
 - Dominate in prolonged activity
 - Fast-twitch muscle fibers (“white” muscles) make ATP by lactate fermentation
 - Have few mitochondria and no myoglobin
 - Sustain short bursts of activity
-

Sprinters and Lactate Fermentation

Key Concepts:

How Anaerobic Pathways End

- *Fermentation pathways start with glycolysis*
 - *Substances other than oxygen accept electrons at the end of the pathways*
 - *Compared with aerobic respiration, the net yield of ATP from fermentation is small*
-

Reflections on Life's Unity

- Life's diversity and continuity arise from unity at the level of molecules and energy
 - Energy inputs drive the organization of molecules into cells (one-way flow of energy)
 - Energy from the sun sustains life's organization
 - Photosynthesizers use energy from the sun to feed themselves and other forms of life
 - Aerobic respiration balances photosynthesis
-

Links Between Photosynthesis and Aerobic Respiration
